Title: A Simple Baseline for Bayesian Uncertainty in Deep Learning. A Simple Baseline for Bayesian Uncertainty in Deep Learning. We propose SWA-Gaussian (SWAG), a simple, scalable, and general purpose approach for uncertainty representation and calibration in deep learning. Stochastic Weight Averaging (SWA), which computes the first moment of stochastic gradient descent (SGD) iterates with a modified learning rate schedule, has recently been shown to improve generalization in deep learning.

a Bayesian deep learning framework combining input-dependent aleatoric uncertainty together with epistemic uncertainty. We study models under the framework with per-pixel semantic segmentation and depth regression tasks. Further, our explicit uncertainty formulation leads to new loss functions for these tasks, which

Deep learning tools have gained tremendous attention in applied machine learning. However such tools for regression and classification do not capture model uncertainty. In comparison, Bayesian models offer a mathematically grounded framework to reason about model uncertainty, but usually come with a prohibitive computational cost.

Dropout as a Bayesian Approximation: Representing Model ...

Bayesian deep learning (BDL) offers a pragmatic approach to combining Bayesian probability theory with modern deep learning. BDL is concerned with the development of techniques and tools for quantifying when deep models become uncertain, a process known as inference in probabilistic modelling.

Bayesian Deep Learning. In their paper Dropout as a Bayesian Approximation: Representing Model Uncertainty in Deep Learning, Garin et al. show that a "multilayer perceptron with arbitrary depth and non-linearities and with dropout applied after every weight layer is mathematically equivalent to an approximation to the deep Gaussian process".

Doing More with Less Using Bayesian Active Learning

There are two factors at play when visualising uncertainty in dropout Bayesian neural networks: the dropout masks and the dropout probability of the first layer. Uncertainty depictions in my previous blog posts drew new dropout masks for each test point—which is equivalent to drawing a new prediction from the predictive distribution for each test point $\mathbb{E}_{\mathbf{x}} \mathbb{E}_{\mathbf{y}} \mathbb{E}_{\mathbf{z}}$.

This time, we will examine what homoscedastic, heteroscedastic, epistemic, and aleatoric uncertainties actually tell you. In my opinion, this is an upcoming research field in Bayesian deep learning and has been greatly shaped by Yarín Gal's contributions. Most illustrations here are taken from his publications.

What Uncertainties tell you in Bayesian Neural Networks ...

Deep learning models typically lack a representation of uncertainty, and provide overconfident and miscalibrated predictions [e.g., 21, 12]. Bayesian methods provide a natural probabilistic representation of uncertainty in deep learning [e.g., 3, 24, 5], and previously had been a gold standard for inference with neural networks.

A Simple Baseline for Bayesian Uncertainty in Deep Learning

Bayesian deep learning models typically form uncertainty estimates by either placing distributions over model weights, or by learning a direct mapping to probabilistic outputs. In this section I'm going to briefly discuss how we can model both epistemic and aleatoric uncertainty using Bayesian deep learning models.

Bayesian Neural Networks seen as an ensemble of learners Bayesian Neural Networks (BNNs) are a way to add uncertainty handling in our models. The idea is simple, instead of having deterministic weights that we learn, we instead learn the parameters of a random variable which we will use to sample our weights during forward propagation.

At the same time, Bayesian inference forms an important share of statistics and probabilistic machine learning (where probabilistic distributions are used to model the learning, uncertainty, and observable states). The primary attraction of BDL is that it offers principled uncertainty estimates from deep learning architectures.
