Molecular Mechanisms of Anesthetic Action via Cellular and Receptor-Mediated Signaling Pathways. The molecular basis of anesthetic action involves membrane proteins (2, 5, 18-21, 110). Primarily and foremost, molecular mechanisms are synaptic, affecting the cysteine-loop superfamily of neurotransmitter receptors and mediating either increases of inhibitory postsynaptic excitability or decreases of presynaptic (excitatory) neurotransmitter release.

Precise understanding of the spatial (i.e. at different subcellular locations such as in the cytosol, mitochondria) and temporal role of redox (i.e. changes in the role of ROS with time) to selectively activate downstream signaling pathways, maintain an intact and continuous EC layer throughout the cardiovascular system, maintain vasodilation in resistance arterioles, and induce a proangiogenic environment in ischemic myocardium is critical for the development of future therapeutic ...
